# Hierarchical interpolative factorization 

Kenneth L. Ho (Stanford)

Joint work with Lexing Ying
Darve Group Meeting, Jan 2014

## Introduction

Elliptic PDEs in differential or integral form:

$$
\begin{aligned}
-\nabla \cdot(a(x) \nabla u(x))+v(x) u(x) & =f(x) \\
a(x) u(x)+\int_{\Omega} K(x, y) u(y) d \Omega(y) & =f(x)
\end{aligned}
$$

- Fundamental to physics and engineering
- Interested in 2D/3D, complex geometry
- Discretize $\rightarrow$ structured linear system $A x=b$

Goal: fast and accurate algorithms for the discrete operators

- Fast matrix-vector multiplication
- Fast solver, good preconditioner
- Linear or nearly linear complexity, high practical efficiency

## Previous work

Fast matrix-vector multiplication

- Trivial for differential operators (sparse)
- Achieved for integral operators by FMM, treecode, $\mathcal{H}$-matrices, etc.

However, fast solvers have been much harder to come by

- Iterative methods
- Number of iterations can be large
- Inefficient for multiple right-hand sides
- Nested dissection/multifrontal, HSS matrices/recursive skeletonization
- Small constants, optimal in quasi-1D
- Rank growth in higher dimensions yields superlinear cost
- $\mathcal{H}$-matrices
- Optimal complexity but large prefactor
- MF/RS with structured matrix algebra
- Improved prefactor, complex geometry can be difficult

Many contributors; apologies for not listing names

Hierarchical interpolative factorization

- MF/RS + recursive dimensional reduction
- Same idea as with using structured algebra but in a new matrix framework
- Explicit sparsification, generalized LU decomposition
- Extends to 3D, complex geometry, etc.

Tools: Schur complement, interpolative decomposition, skeletonization

## Schur complement

Let

$$
A=\left[\begin{array}{ccc}
A_{p p} & A_{p q} & \\
A_{q p} & A_{q q} & A_{q r} \\
& A_{r q} & A_{r r}
\end{array}\right] .
$$

(Think of $A$ as a sparse matrix.) If $A_{p p}$ is nonsingular, define

$$
R_{p}^{*}=\left[\begin{array}{ccc}
I & & \\
-A_{q p} A_{p p}^{-1} & & \\
& & I
\end{array}\right], \quad S_{p}=\left[\begin{array}{ccc}
I & -A_{p p}^{-1} A_{p q} & \\
& I & \\
& & I
\end{array}\right]
$$

so that

$$
R_{p}^{*} A S_{p}=\left[\begin{array}{ccc}
A_{p p} & & \\
& * & A_{q r} \\
& A_{r q} & A_{r r}
\end{array}\right] .
$$

- DOFs $p$ have been eliminated
- Interactions involving $r$ are unchanged

If $A_{:, q}$ is numerically low-rank, then there exist

- redundant ( $\check{q}$ ) and skeleton ( $\hat{q}$ ) columns partitioning $q=\check{q} \cup \hat{q}$
- an interpolation matrix $T_{q}$ with $\left\|T_{q}\right\|$ small
such that

$$
A_{:, \check{q}} \approx A_{:, \hat{q}} T_{q} .
$$

- Essentially an RRQR written slightly differently
- Can be computed adaptively to any specified precision
- Fast randomized algorithms are available

Interactions between separated regions are low-rank.

## Skeletonization

- Use ID + Schur complement to eliminate redundant DOFs
- Let $A=\left[\begin{array}{ll}A_{p p} & A_{p q} \\ A_{q p} & A_{q q}\end{array}\right]$ with $A_{p q}$ and $A_{q p}$ low-rank
- Apply ID to $\left[\begin{array}{c}A_{q p} \\ A_{p q}^{*}\end{array}\right]:\left[\begin{array}{c}A_{q \check{p}} \\ A_{\hat{p} q}^{*}\end{array}\right] \approx\left[\begin{array}{c}A_{q \hat{p}} \\ A_{\hat{p} q}^{*}\end{array}\right] T_{p} \Longrightarrow \begin{gathered}A_{q \check{p}} \approx A_{q \hat{p}} T_{p} \\ A_{\check{p} q} \approx T_{p}^{*} A_{\hat{p} q}\end{gathered}$
- Reorder $A=\left[\begin{array}{lll}A_{\check{\rho} \check{\rho}} & A_{\breve{\rho} \hat{\rho}} & A_{\check{\rho} q} \\ A_{\hat{\rho} \check{\rho}} & A_{\hat{\rho} \hat{\rho}} & A_{\hat{\rho} q} \\ A_{q \check{\rho}} & A_{q \hat{\rho}} & A_{q q}\end{array}\right]$, define $Q_{p}=\left[\begin{array}{ccc}1 & & \\ -T_{p} & 1 & \\ & & I\end{array}\right]$
- Sparsify via ID: $Q_{p}^{*} A Q_{p} \approx\left[\begin{array}{ccc}* & * & \\ * & A_{\hat{\rho} \hat{p}} & A_{\hat{\rho} q} \\ & A_{q \hat{p}} & A_{q q}\end{array}\right]$
- Schur complement: $R_{p}^{*} Q_{p}^{*} A Q_{p} S_{p} \approx\left[\begin{array}{cccc}* & & \\ & * & A_{\hat{p} q} \\ & A_{q \hat{p}} & A_{q q}\end{array}\right]$

## Differential equations

## Algorithm: multifrontal

Build quadtree/octree.
for each level $\ell=0,1,2, \ldots, L$ from finest to coarsest do
Let $C_{\ell}$ be the set of all cells on level $\ell$.
for each cell $c \in C_{\ell}$ do
Schur complement remaining interior DOFs in $c$. end for end for

## MF analysis

- Schur complement operator (assume SPD):

$$
W_{\ell}=\prod_{c \in C_{\ell}} S_{c}
$$

- Block diagonalization:

$$
D \approx W_{L-1}^{*} \cdots W_{0}^{*} A W_{0} \cdots W_{L-1}
$$

- LU decomposition:

$$
\begin{aligned}
A & \approx W_{0}^{-*} \cdots W_{L-1}^{-*} D W_{L-1}^{-1} \cdots W_{0}^{-1} \\
A^{-1} & \approx W_{0} \cdots W_{L-1} D^{-1} W_{L}^{*} \cdots W_{0}^{*}
\end{aligned}
$$

- Numerically exact: fast direct solver

MF analysis

The cost is determined by the separator/front size.

|  | 1 D | 2 D | 3 D |
| :--- | :---: | :---: | :---: |
| Front size | $\mathcal{O}(1)$ | $\mathcal{O}\left(N^{1 / 2}\right)$ | $\mathcal{O}\left(N^{2 / 3}\right)$ |
| Factorization cost | $\mathcal{O}(N)$ | $\mathcal{O}\left(N^{3 / 2}\right)$ | $\mathcal{O}\left(N^{2}\right)$ |
| Solve cost | $\mathcal{O}(N)$ | $\mathcal{O}(N \log N)$ | $\mathcal{O}\left(N^{4 / 3}\right)$ |

Question: How to reduce the front size in 2D and 3D?

- Frontal matrices are dense but rank-structured
- Exploit separator geometry by skeletonizing along edges
- Dimensional reduction

Algorithm: hierarchical interpolative factorization in 2D

Build quadtree.
for each level $\ell=0,1,2, \ldots, L$ from finest to coarsest do
Let $C_{\ell}$ be the set of all cells on level $\ell$.
for each cell $c \in C_{\ell}$ do
Schur complement remaining interior DOFs in $c$.
end for
Let $C_{\ell+1 / 2}$ be the set of all edges on level $\ell$.
for each cell $c \in C_{\ell+1 / 2}$ do
Skeletonize remaining interior DOFs in $c$.
end for
end for

## Algorithm: hierarchical interpolative factorization in 3D

Build octree.
for each level $\ell=0,1,2, \ldots, L$ from finest to coarsest do
Let $C_{\ell}$ be the set of all cells on level $\ell$.
for each cell $c \in C_{\ell}$ do
Schur complement remaining interior DOFs in $c$.
end for
Let $C_{\ell+1 / 2}$ be the set of all faces on level $\ell$.
for each cell $c \in C_{\ell+1 / 2}$ do
Skeletonize remaining interior DOFs in $c$.
end for
end for

- Can also do additional skeletonization along edges for true linear complexity
- This algorithm is sufficient for $\mathcal{O}(N \log N)$ and better exploits sparsity

## HIF-DE analysis

- Skeletonization operator (assume SPD):

$$
U_{\ell}=\prod_{c \in C_{\ell}} Q_{c} S_{c}
$$

- Generalized LU decomposition:

$$
\begin{aligned}
A & \approx W_{0}^{-*} U_{1 / 2}^{-*} \cdots W_{L-1}^{-*} U_{L-1 / 2}^{-*} D U_{L-1 / 2}^{-1} W_{L-1}^{-1} \cdots U_{1 / 2}^{-1} W_{0}^{-1} \\
A^{-1} & \approx W_{0} U_{1 / 2} \cdots W_{L-1} U_{L-1 / 2} D^{-1} U_{L-1 / 2}^{*} W_{L}^{*} \cdots U_{1 / 2}^{*} W_{0}^{*}
\end{aligned}
$$

- No longer exact, fast direct solver or preconditioner depending on accuracy

## Conclusions

- Linear-time algorithm for structured operators in 2D and 3D
- Fast matrix-vector multiplication
- Fast direct solver at high accuracy, preconditioner otherwise
- Main novelties:
- Dimensional reduction by alternating between cells, faces, and edges
- Matrix factorization via new linear algebraic formulation
- Explicit elimination of DOFs, no nested hierarchical operations
- Can be viewed as adaptive numerical upscaling
- Extensions: $A^{1 / 2}, \log \operatorname{det} A, \operatorname{diag} A^{-1}$
- High accuracy for IEs in 3D still challenging, may require new ideas
- Perspective: structured dense matrices can be sparsified very efficiently
- Can borrow directly from sparse algorithms, e.g., RS = MF
- What other features of sparse matrices can be exploited?
